VII. Supersymmetric extension of the Standard Model (finally!)

Steps to construct a supersymmetric extension of the Standard Model:

1. Add a superpartner to all Standard Model particles such that:
   \[ \text{Str 1} = n_B - n_F = 0 \]

2. In step 1, new fermions are added which can generate a gauge anomaly. This will require a slight extension of the original Standard Model.

The standard model contains a Higgs boson with quantum numbers \((1, 2, 1)\) under \(SU(3) \times SU(2) \times U(1)\).

\[ \text{color weak hypercharge singlet doublet} \quad Y = 1. \]

Its higgsino partner will generate an anomaly. To avoid this problem, add a second Higgs doublet with opposite hypercharge: \((1, 2, -1)\). Now, the supersymmetric extended model contains two pairs of higgsinos

\[(1, 2, 1) \oplus (1, 2, -1)\]

which is now vector-like rather than chiral; the total contribution to the gauge anomalies cancel.
Cancellation of anomalies:

\[ \text{Tr } T_3^a Y = 0 \quad \text{Tr } Y^3 = 0 \]

(Remember the color factor when performing the trace!)

For example, for the Standard Model fermions,

\[
(\text{Tr } Y^3)_{\text{SM}} = 3 \left( \frac{1}{27} + \frac{1}{27} - \frac{6}{27} + \frac{8}{27} \right) - 1 - 1 + 8 = 0
\]

If we just had one Higgs doublet, then the (left-handed) Higgsino superpartners would be \( (\tilde{H}^+, \tilde{H}^0) \) with \( T_3 = \pm \frac{1}{2} \) and \( Y = 1 \). Then, \( \text{Tr } Y^3 = (\text{Tr } Y^3)_{\text{SM}} + 2 \).

(Note: the only other supersymmetric fermions — the gauginos — have \( Y = 0 \) and so do not contribute to the anomaly or its cancellation.)

By including Higgs multiplets in pairs, with opposite hypercharge, the Higgsinos' contributions to the anomaly will cancel.

Finally, it is worth pointing out that if we require the cancellation of pure gravitino and mixed gravitational/gauge anomalies (by substituting some or all gauge bosons above with gravitons), we deduce one more new requirement: \( \text{Tr } Y = 0 \). Again this implies that we must include Higgs doublets in pairs with opposite hypercharge.
3. Include supersymmetric interactions

As we shall see, the most general set of allowed interactions contain some terms that violate baryon number $B$ or lepton number $L$. These can be removed if a particular discrete symmetry is imposed.

4. Break the supersymmetry by adding the most general set of soft-supersymmetry breaking terms.

The result of steps 1–4:

The minimal supersymmetric extension of the Standard Model (MSSM). The MSSM is defined such that all $B$ and $L$ violating interactions are forbidden by a discrete symmetry.

To go beyond the MSSM, either:

(i) allow for some $B$ or $L$ violation at step 3
(ii) extend the matter sector of the MSSM and repeat steps 1–4
(iii) extend the gauge sector of the MSSM and repeat steps 1–4.
A summary of supersymmetric interactions

1. Self-interaction of the gauge supermultiplet
   
   origin of terms: \( \frac{1}{2} \int d^4 \Theta \, \text{tr} \, W^a W_a + \text{h.c.} \)
   
   - self-coupling of gauge fields [dictated by non-abelian gauge theory]
   - coupling of the gauge field to the gauginos
     (also fixed by the non-abelian gauge theory)

2. Interaction of the gauge and matter supermultiplet
   
   origin of terms: \( \int d^4 \Theta \, \overline{\phi} e^{2g V} \phi \)
   
   - coupling of the gauge field to spin-0 matter
   - coupling of the gauge field to spin-½ matter
     (these two are fixed by gauge invariance)
   - coupling of the gaugino to spin-½ matter and its superpartner

   \[ L = -i e g \left( \overline{\chi^a} T^a \gamma_j A_j - A^* \, T^a \gamma_j \psi_j \right) \]
   
   this is a consequence of the supersymmetry

3. Self-interaction of the matter supermultiplet
   
   - scalar potential
     \[ V_{\text{scalar}} = \sum_i F_i^* F_i + \frac{1}{2} [D^a D_a + (D')^2] \]
     if the gauge group contains a \( U(1) \) factor
   
   - Yukawa interactions
     \[ L = -\frac{1}{2} \left[ \frac{d^2 W}{dA_i dA_j} \, \psi_i \psi_j + (\frac{d^2 W}{dA_i dA_j})^* \overline{\psi}_i \overline{\psi}_j \right] \]
     origin of these two terms: \( \int d^2 \Theta \, W(\phi) + \text{h.c.} \)
The spectrum of the MSSM

The matter multiplets of the MSSM originate from chiral superfields:
\[
\hat{L}, \hat{E}, \hat{Q}, \hat{U}, \hat{D}, \hat{H}_1, \text{ and } \hat{H}_2
\]
where hats will be used to indicate superfields.
For example,
\[
\hat{E} = A_E + \sqrt{2} \theta \psi_E - \theta \theta F_E
\]
with \(A_E = \hat{e}_R^t\) and \((\psi_E) = P_L e^t = e_L^t\).

**Supersymmetric interactions**

The SUSY interactions are known once we specify the superpotential. The most general gauge invariant superpotential has the following form:

\[
W = W_R + W_{NR}
\]

where

\[
W_R = E_{ij} \left[ h_{ij} \hat{H}_1^i \hat{H}_1^j \hat{E}^t + h_{ij} \hat{H}_2^i \hat{Q}^t \hat{D}^t + h_{ij} \hat{H}_2^i \hat{Q}^t \hat{U}^t - \mu \hat{H}_1^i \hat{H}_2^j \right]
\]
i and j are weak SU(2) indices. Here \(E_{12} = -E_{21} = +1\).
\(\mu\) = supersymmetric Higgs mass parameter.

Generation labels have been suppressed; \(h_{ij}\), \(h_{ih}\) and \(h_{ij}\) are actually 3×3 matrices. In a one-generation model,

\[
h_L = \frac{\sqrt{2} v_1}{v_1}, \quad h_b = \frac{\sqrt{2} m_b}{v_1}, \quad h_t = \frac{\sqrt{2} m_t}{v_2}
\]
where \(\langle H_1^0 \rangle = \frac{v_1}{\sqrt{2}}, \quad \langle H_2^0 \rangle = \frac{v_2}{\sqrt{2}}\).
\[ W_{NR} = \delta_{i j} \left[ \lambda_L \hat{\lambda}^i \hat{\lambda}^j \hat{E} + \lambda'_L \hat{\lambda}^i \hat{Q}^j \hat{D} - \mu \hat{\lambda}^i \hat{H}^0 \right] + \lambda_B \hat{U} \hat{D} \hat{D} \]

where generation labels are again suppressed. Note that \( \lambda_L \) must be antisymmetric upon interchange of \( \hat{\lambda}^i \) and \( \hat{\lambda}^j \).

One quickly observes that the terms in \( W_{NR} \) violate either baryon number (B) or lepton number (L):

\[
\begin{align*}
\hat{L} \hat{C} \hat{E}, & \hat{L} \hat{Q} \hat{D}, \hat{L} \hat{A} \\
\hat{O} \hat{D} \hat{D} & \Delta L \neq 0 \\
\Delta B & \neq 0
\end{align*}
\]

In the MSSM, set \( W_{NR} = 0 \).

In this regard, the MSSM is not as elegant as the SM. Recall that if one imposes \( SU(3)_C \times SU(2)_L \times U(1)_Y \) on all possible SM interactions, one finds that all terms of dimension \( \leq 4 \) preserve B and L. Not so in supersymmetry!

How does one impose \( W_{NR} = 0 \)?

Here, we introduce a discrete symmetry to do our dirty work. Two equivalent descriptions:

1. Matter parity

The MSSM does not distinguish Higgs and Quark/Lepton Superfields. Define matter parity such that all Quark/Lepton Superfields change sign but the Higgs superfields do not.
2. R-parity

In superspace, a chiral superfield is
\[ \hat{\Phi} = A(x) + \sqrt{2} \theta \Psi(x) + \theta \Theta F(x) \]

Under a continuous \( U(1)_R \) symmetry, \( \theta \to e^{i \alpha} \theta \)
and \( \hat{\Phi} \to e^{i \alpha} \hat{\Phi} \). The superfield has \( R = n \). This means
that the component fields have \( R(A) = n, R(\Psi) = n-1, R(F) = n-2 \).
The superpotential \( W \) must have \( R(W) = 2 \) in order that the
theory conserve \( U(1)_R \), since \( [W]_F + h.c. \) appears in the
supersymmetric Lagrangian.

Thus, to set \( W_{NR} = 0 \), choose
\[ R = 1 \quad \text{for} \quad \hat{A}_1, \hat{A}_2, \]
\[ R = \frac{1}{2} \quad \text{for} \quad \hat{L}, \hat{E}, \hat{Q}, \hat{U}, \hat{D} \]

In fact, \( U(1)_R \) is too restrictive. Consider the gauge supermultiplet, \( \hat{V} \).
Since \( \hat{V} \) is real, we must have \( R(\hat{V}) = 0 \) which means that
\( R(\hat{V}_u) = 0, \ R(\lambda) = 1 \). That is, \( U(1)_R \) forbids Majorana masses for
the gaugino.

In the MSSM, we will add Majorana mass terms for the gaugino
via the soft-SUSY-breaking terms. Since these terms are quadratic
in \( \lambda \), we see that \( U(1)_R \) is broken to a discrete \( \mathbb{Z}_2 \) symmetry
called R-parity. It is easy to check that:
\[ R = (-1)^{3(B-L)+2S} \]
for particles of spin \( S \). By imposing R-parity invariance, \( W_{NR} = 0 \).
At this point, our model consists of a supersymmetric gauge field theory based on $SU(3) \times SU(3) \times U(1)$. But, it is not yet realistic for two reasons:

- supersymmetry is an exact symmetry
- $SU(2) \times U(1)$ is unbroken

To illustrate the second point, examine the scalar potential:

$$V_{\text{scalar}} = \sum_i F_i^* F_i + \frac{1}{2} [D^a D^a + (D')^2]$$

The result:

$$V_{\text{Higgs}} = \mu^2 \left[ |H_1|^2 + |H_2|^2 \right] \quad \text{from the F-terms}$$

$$+ \frac{1}{8} (g^2 + g'^2) \left[ |H_1|^2 - |H_2|^2 \right]^2 + \frac{1}{2} g^2 |H_1^* H_2|^2 \quad \text{from the D-terms}$$

(exercise: derive this!)

Clearly, $V_{\text{Higgs}} \geq 0$ and $H_1 = H_2 = 0$ minimizes the Higgs potential (giving $\langle V_{\text{Higgs}} \rangle = 0$ as expected for a supersymmetric vacuum). Hence, no $SU(2) \times U(1)$ breaking.

We shall see that the addition of soft-SUSY-breaking terms will also permit the breaking of the electroweak symmetry.
**Soft-SUSY-breaking terms**

Assume R-parity invariance

**notation:** \( \tan \beta \equiv \frac{v_2}{v_1} \) \( v^2 \equiv v_1^2 + v_2^2 = (246 \text{ GeV})^2 \)

\[ m_W = \frac{1}{2} g v \]

\[ V_{\text{soft}} = \left( m_{H_1}^2 |H_1|^2 + m_{H_2}^2 |H_2|^2 \right) - m_{1/2} \left( \varepsilon_{ij} H_i^* H_j^* + h.c. \right) \]

\[ + M_Q (\tilde{e}_L \tilde{e}_L + \tilde{d}_L \tilde{d}_L) + M_U \tilde{t}_R \tilde{t}_R + M_D \tilde{b}_R \tilde{b}_R \]

\[ + M_L (\tilde{\nu}^* \tilde{\nu} + \tilde{\tau}^* \tilde{\tau}) + M_E \tilde{\tau}_R \tilde{\tau}_R \]

\[ + \frac{g}{\sqrt{2} m_W} \varepsilon_{ij} \left[ \frac{m_t A_t}{\cos \beta} H_i^* \tilde{L}^* \tilde{e}_L + \frac{m_b A_b}{\cos \beta} H_i^* \tilde{L}^* \tilde{d}_L \right] \]

\[ + \frac{m_t A_t}{\sin \beta} H_2^* \tilde{\nu}_i \tilde{\nu}_j^* \]

\[ + \frac{1}{2} \left[ M_3 \tilde{\nu} \tilde{\nu} + M_2 \tilde{w}^a \tilde{w}^a + M_1 \tilde{b} \tilde{b}^c + h.c. \right] \]

where \( \tilde{L}_L = (\tilde{\nu}_L \tilde{e}_L) \) and \( \tilde{\nu}_L = (\tilde{\nu}_\mu \tilde{\nu}_	au) \). I have written this for the case of one generation. For three generations, \( M_Q, M_U, M_D, M_L, M_E \) are 3x3 matrices.

**color code**

- Scalar soft squared-mass terms
- B-term \( m_{1/2} \equiv b = B/\mu \)
- A-terms
- Gaugino Majorana mass terms
Mass Eigenstates of the MSSM

By examining the contributions of $S_{Q}$ and $V_{soft}$ to the quadratic terms, we discover that any set of particles of a given spin, $B$ and $L$, and $SU(3)_{c} \times U(1)_{em}$ can mix. Thus, we must diagonalize mass matrices to obtain the mass eigenstates and the corresponding mass eigenvalues.

(iii) scalar-quark sector

In principle, I must diagonalize 6×6 matrices corresponding to the basis $(\tilde{q}_{iL}, \tilde{q}_{iR})$, $i=1,2,3$ ← generation labels.

To make these transformations readable, I shall only display the one-generation case.

\[
M_{\tilde{t}} = \begin{bmatrix}
M_{\tilde{t}}^2 + m_{t}^2 + m_{c}^2 \cos^{2} \beta \left( \frac{1}{2} - e_{u} s_{w}^2 \right) & m_{t} (A_{t} - \mu \cot \beta) \\

m_{t} (A_{t} - \mu \cot \beta) & M_{\tilde{u}}^2 + m_{t}^2 + m_{c}^2 \cos^{2} \beta e_{u} s_{w}^2
\end{bmatrix}
\]

\[
M_{\tilde{b}} = \begin{bmatrix}
M_{\tilde{b}}^2 + m_{b}^2 - m_{c}^2 \cos^{2} \beta \left( \frac{1}{2} + e_{d} s_{w}^2 \right) & m_{b} (A_{b} - \mu \tan \beta) \\

m_{b} (A_{b} - \mu \tan \beta) & M_{\tilde{d}}^2 + m_{b}^2 + m_{c}^2 \cos^{2} \beta e_{d} s_{w}^2
\end{bmatrix}
\]

where $e_{u} = \frac{1}{3}$, $e_{d} = -\frac{1}{3}$, $s_{w}^2 = \sin^{2} \Theta_{w}$ and $\tan \beta = \langle H_2 \rangle / \langle H_1 \rangle$. 
(ii) scalar-lepton sector

\[ M^2 = M^2_L + \frac{1}{2} m^2_Z \cos 2\beta \]

\[ M^2_{l} = \begin{bmatrix}
M^2_L + m^2_{l} - m^2_Z \cos 2\beta \left( \frac{1}{2} - s^2_w \right) & m_t (A_t - \mu \tan \beta) \\

m_t (A_t - \mu \tan \beta) & m^2_L + m^2_{l} - m^2_Z \cos 2\beta s^2_w 
\end{bmatrix} \]

These results suggest that \( \tilde{f}_L - \tilde{f}_R \) mixing is unimportant in the first two generations. In the third generation, top-squark ("stop") mixing is likely to be the most significant, while bottom-squark ("stop") mixing and tau-slepton ("stau") mixing may also be relevant if \( \tan \beta \gg 1 \).

Remark: expectations for \( \tan \beta \)

The Higgs-fermion Yukawa coupling are:

\[ h_b = \frac{\sqrt{2} m_b}{v_1} = \frac{\sqrt{2} m_b}{v \cos \beta}, \quad h_\tau = \frac{\sqrt{2} m_\tau}{v_2} = \frac{\sqrt{2} m_\tau}{v \sin \beta} \]

Perturbativity of couplings suggest that \( h_b \) and \( h_\tau \) should not be too large. This would imply (crudely) that:

\[ 1 \leq \tan \beta \leq \frac{m_\tau}{m_b} \]

(More convincing arguments exist, but will not be given here.)
Charginos are mixtures of gauginos and higgsinos. They arise from the SUSY-interaction

\[ -\mathcal{L} = i\sqrt{2} g^a (\bar{\chi}^a \gamma^i T^a_i A_j - A_i^a \gamma^i \chi^a \gamma^j) \]

when the Higgs bosons acquire their vacuum expectation values. Two other sources for mass terms are:

(i) \[ -\mathcal{L} = \frac{1}{2} \left( \frac{d^2 W}{dA_i dA_j} \right) \psi_i \psi_j \] due to the \( \mu \)-term

(ii) soft-SUSY-breaking Majorana mass term for the gaugino.

Writing

\[ -\mathcal{L}_{\text{mass}} = \frac{1}{2} (\psi^+ \psi^-) \begin{pmatrix} 0 & X^T \\ X & 0 \end{pmatrix} (\psi^+ - \psi^-) + \text{h.c.} \]

with:

\[ \psi^+ = (-i \lambda^+ \psi_{H_2}^+) \]

\[ \psi^- = (-\alpha \lambda^- \psi_{H_1}^-) \]

we find:

\[ \chi = \begin{pmatrix} M_2 & g v_2 \\ g v_1 & \mu \end{pmatrix} = \begin{pmatrix} M_2 \sqrt{2} m_w \sin \beta \\ \sqrt{2} m_w \cos \beta \end{pmatrix} \]

Mass diagonalization works as follows. Let:

\[ \chi_i^+ = U_{ij} \psi_j^+ \]

\[ \chi_i^- = U_{ij} \psi_j^- \]

\( D, U \) unitary
Then,
\[-L_{\text{mass}} = \sum_{ij} (M_D)_{ij} \chi_i^+ \chi_j^- + h.c.\]

where \(M_D\) is a diagonal matrix with positive entries and:
\[U^T X V^{-1} = M_D\]

To determine \(U\) and \(V\), note that:
\[M_D^T M_D = V X^T X V^{-1}\]
\[M_D M_D^T = U^* X X^+ U^*^{-1}\]

so all we have to do is to diagonalize \(X^+ X\) and \(X X^+\) and adjust the relative phases of \(U^*\) and \(V\) such that the entries of \(M_D\) are positive.

The chargino masses are the positive square roots of the eigenvalues of \(X^+ X\) (or \(X X^+\)):
\[m^2_{\tilde{\chi}_i^\pm} = \frac{1}{2} \left[ |\mu|^2 + |M_2|^2 + 2m_w^2 \right.\]
\[- \left. \left[ (|\mu|^2 + |M_2|^2 + 2m_w^2)^2 - 4 |\mu|^2 |M_2|^2 \right]^{1/2} \right.\]
\[- 4m_w^2 \sin 2\beta \left. + 8m_w^2 \sin 2\beta \Re(\mu M_2) \right]^{1/2}\]

Eigenstates: \(\tilde{\chi}_1^\pm, \tilde{\chi}_2^\pm\) with \(m_{\tilde{\chi}_1} < m_{\tilde{\chi}_2}\).
Neutralinos are mixtures of neutral gauginos and higgsinos. Following the previous analysis, we obtain:

\[-\mathcal{L}_{\text{mass}} = \frac{1}{2} \psi^0_i \psi^0_j \gamma^0 + \text{h.c.}\]

with

\[
\psi^0 = (-\chi' - i \chi^3 \psi^0_{H_1} \psi^0_{H_2})
\]

\(\chi'\) is the hypercharge gaugino ("bino")

\(\chi^3\) is the \(W^3\)-gaugino ("wino")

and

\[
Y = \begin{pmatrix}
M_1 & 0 & -m_2 \sin \phi \mu & m_2 \sin \phi \mu \\
0 & M_2 & m_2 \cos \phi \mu & -m_2 \cos \phi \mu \\
-m_2 \sin \phi \beta & m_2 \cos \phi \beta & 0 & -\mu \\
m_2 \sin \phi \beta & -m_2 \cos \phi \beta & -\mu & 0
\end{pmatrix}
\]

Mass diagonalization:

\[
\chi_i^0 = N_{ij} \psi_j^0
\]

\[-\mathcal{L}_{\text{mass}} = \chi_i^0 (M_D)_{ij} \chi_j^0 + \text{h.c.}\]

Then:

\[N^T Y N^{-1} = M_D\]

The phases of \(N\) can be adjusted such that all entries of the diagonal matrix \(M_D\) are positive.

\[
\begin{align*}
S_w = \sin \theta_w \\
C_w = \cos \theta_w \\
S_\beta = \sin \beta \\
C_\beta = \cos \beta
\end{align*}
\]
Limiting cases for the neutralino mass matrix:

(i) \( M_1 = M_2 = \mu = 0 \)

\[
\begin{align*}
\tilde{\chi}_1^0 &= \tilde{\xi} \\
\tilde{\chi}_2^0 &= \tilde{H}_1^0 \sin \beta + \tilde{H}_2^0 \cos \beta \\
\tilde{\chi}_3^0 &= \sqrt{\frac{1}{2}} \left[ \tilde{Z} + \tilde{H}_i^0 \cos \beta - \tilde{H}_2^0 \sin \beta \right] \\
\tilde{\chi}_4^0 &= \sqrt{\frac{1}{2}} \left[ -\tilde{Z} + \tilde{H}_i^0 \cos \beta - \tilde{H}_2^0 \sin \beta \right]
\end{align*}
\]

where

\[
\begin{align*}
\tilde{\xi} &= c_W \tilde{B} + s_W \tilde{W}_3 \quad \text{"photino"} \\
\tilde{Z} &= -s_W \tilde{B} + c_W \tilde{W}_3 \quad \text{"zino"}
\end{align*}
\]

Clearly, nature is not very close to this limit.

(ii) \( M_1, M_2, |\mu| \gg m_2 \)

\[
\tilde{\chi}_2^0 = \{ \tilde{B}, \tilde{W}_3, \frac{1}{\sqrt{2}} (\tilde{H}_1^0 - \tilde{H}_2^0), \frac{1}{\sqrt{2}} (\tilde{H}_1^0 + \tilde{H}_2^0) \}
\]

with masses \( |M_1|, |M_2|, ||\mu|\| \) and \( ||\mu|\| \) respectively.

Standard notation: \( m_{\tilde{\chi}_1^0} < m_{\tilde{\chi}_2^0} < m_{\tilde{\chi}_3^0} < m_{\tilde{\chi}_4^0} \).
(v) The MSSM Higgs sector

Including the soft-SUSY-breaking terms, the Higgs potential is given by:

\[ V_{\text{Higgs}} = m_1^2 |H_1|^2 + m_2^2 |H_2|^2 - \left( m_{12}^2 \varepsilon_{ij} H_i^* H_j^* + h.c. \right) \]

\[ + \frac{1}{8} (g^2 + g'^2) \left( |H_1|^2 - |H_2|^2 \right)^2 + \frac{1}{2} g^2 |H_1^* H_2|^2 \]

where:

\[ m_1^2 \equiv \mu^2 + m_{H_1}^2 \]

\[ m_2^2 \equiv \mu^2 + m_{H_2}^2 \]

Let us search for a minimum where

\[ \langle H_1 \rangle = \frac{1}{\sqrt{2}} \left( \begin{array}{c} v_1 \\ 0 \end{array} \right) \]

\[ \langle H_2 \rangle = \frac{1}{\sqrt{2}} \left( \begin{array}{c} 0 \\ v_2 \end{array} \right) \]

where the vacuum expectation values (v.e.v.'s) appear in the charge-neutral components.

\[ \langle V_{\text{Higgs}} \rangle = \frac{1}{2} m_1^2 v_1^2 + \frac{1}{2} m_2^2 v_2^2 - m_{12}^2 v_1 v_2 + \frac{1}{32} (g^2 + g'^2) (v_2^2 - v_1^2)^2 \]

Minimize this:

\[ \frac{d}{dv_1} \langle V_{\text{Higgs}} \rangle = 0 \]

\[ m_1^2 = m_{12}^2 \frac{v_2}{v_1} + \frac{1}{8} (g^2 + g'^2) (v_2^2 - v_1^2) \]

\[ \frac{d}{dv_2} \langle V_{\text{Higgs}} \rangle = 0 \]

\[ m_2^2 = m_{12}^2 \frac{v_1}{v_2} - \frac{1}{8} (g^2 + g'^2) (v_2^2 - v_1^2) \]
We can write:

\[
\langle V_{\text{Higgs}} \rangle = \frac{1}{32} (g_1^2 g_2^2) (v_1^2 - v_2^2) \left( \frac{m_1^2 - m_{12}^2}{-m_{12}^2 + m_2^2} \right) \langle v_1 \rangle.
\]

Then, for the vev's to correspond to a potential minimum,

\[
\det \begin{pmatrix} m_1^2 & -m_{12}^2 \\ -m_{12}^2 & m_2^2 \end{pmatrix} < 0
\]

or \[m_1^2 m_2^2 < m_{12}^4\].

A second condition arises, since for \(v_1 = v_2\), \(\langle V_{\text{Higgs}} \rangle = \frac{V_2^2}{2} (m_1^2 + m_2^2 - 2m_{12}^2)\), which would be unbounded from below unless:

\[m_1^2 + m_2^2 \geq 2m_{12}^2\]

**Technicality:** In obtaining the above two conditions, I assumed that \(m_{13}^2, v_1\) and \(v_2\) are real. However, I can always absorb the phase of \(m_{12}^2\) into the definition of one of the Higgs fields and without loss of generality take \(v_1 > 0\) (by an appropriate hypercharge rotation). Then, the minimum conditions imply that \(v_2\) is real. Finally, I can choose \(v_2 > 0\) by absorbing a potential sign into the definition of \(H_2\).
To compute the Higgs mass spectrum, we write:

\[
H_1 = \frac{1}{\sqrt{2}} \left( \begin{array}{c} v_1 + h_1^0 + i a_1^0 \\ h_1^- \end{array} \right) \quad H_2 = \frac{1}{\sqrt{2}} \left( \begin{array}{c} h_2^+ \\ v_2 + h_2^0 + i a_2^0 \end{array} \right)
\]

From the potential, we compute the quadratic terms in the scalar fields to derive squared-mass matrices. Diagonalizing these matrices yield the physical states:

\[(h_1^0, h_2^0) \longrightarrow h^0, H^0 \]

CP-even Higgs bosons with \( m_h < m_H \)

\[(a_1^0, a_2^0) \longrightarrow A^0, G^0 \]

CP-odd Higgs boson

\[(h_1^\pm, h_2^\pm) \longrightarrow H^\pm, G^\pm \]

charged Higgs bosons

Goldstone bosons that give mass to the \( Z^0 \)

Goldstone bosons that give mass to the \( W^\pm \)

Physical Higgs degrees of freedom = 5

\[ h^0, H^0, A^0, H^\pm \]

+ 3 Goldstone bosons = 8 degrees of freedom of the two complex Higgs doublets
**CP-even Higgs mass matrix:**

\[
M_{ij}^2 = \frac{\partial^2 \langle V_{\text{Higgs}} \rangle}{\partial v_i \partial v_j} = \frac{1}{v_i^2 + v_j^2} \begin{pmatrix} m_A^2 v_2^2 + m_2^2 v_1^2 & -(m_A^2 + m_2^2) v_1 v_2 \\ -(m_A^2 + m_2^2) v_1 v_2 & m_A^2 v_1^2 + m_2^2 v_2^2 \end{pmatrix}
\]

Where:

\[
m_A^2 \equiv \frac{M_2^L}{v_1 v_2} (v_1^2 + v_2^2)
\]

\[
m_2^2 = \frac{1}{4} (g^2 + g'^2) (v_1^2 + v_2^2)
\]

**Eigenvalues**

\[
m_{h,h}^2 = \frac{1}{2} \left[ m_A^2 + m_2^2 \pm \sqrt{(m_A^2 + m_2^2)^2 - 4 m_A^2 m_2^2 \cos^2 2\beta} \right]
\]

Where

\[
\tan \beta \equiv \frac{v_2}{v_1}
\]

**Note:**

\[
v_1^2 + v_2^2 = (2.46 \text{ GeV})^2
\]

**Eigenstates**

\[
h = -h_1^0 \sin \alpha + h_2^0 \cos \alpha
\]

\[
H = h_1^0 \cos \alpha + h_2^0 \sin \alpha
\]

where the CP-even Higgs mixing angle is given by:

\[
\cos 2\phi = -\cos 2\beta \left( \frac{m_A^2 - m_2^2}{m_H^2 - m_h^2} \right)
\]

In our convention, \( v_1 > 0, v_2 > 0 \) implies that \( \sin 2\beta > 0 \).

Hence,

\[
0 < \beta < \frac{\pi}{2}
\]

\[-\frac{\pi}{2} < \alpha < 0\]
\[ M_{\text{odd}} = m_{H^0}^2 \begin{pmatrix} v_2 / v_1 & 1 \\ 1 & v_1 / v_2 \end{pmatrix} \]

eigenvalues: \[ m_0 = 0 \]
[\[ m_A^2 = \text{Tr} M_{\text{odd}}^2 = \frac{m_{H^0}^2}{v_1 v_2} (v_1^2 + v_2^2) \]

\[ M_{\text{charged}} = \left( \frac{m_{W^\pm}^2}{v_1 v_2} + \frac{1}{4} g^2 \right) \begin{pmatrix} v_2^2 & v_1 v_2 \\ v_1 v_2 & v_1^2 \end{pmatrix} \]

eigenvalues: \[ m_0^\pm = 0 \]
[\[ m_{H^\pm}^2 = \text{Tr} M_{\text{charged}}^2 = \left( \frac{m_{W^\pm}^2}{v_1 v_2} + \frac{1}{4} g^2 \right) (v_1^2 + v_2^2) \]

note: \[ m_{H^\pm}^2 = m_W^2 + m_A^2 \]
[since \[ m_W^2 = \frac{1}{4} g^2 (v_1^2 + v_2^2) \].]

A possible phenomenological disaster?

The mass formula for \( m_h \) implies that:
[\[ m_h^2 \leq m_0^2 \cos^2 2\beta \leq m_Z^2 \]

But the LEP Higgs search found no significant evidence for a Higgs boson. Their MSSM Higgs analysis concluded that:
[\[ m_h > 91 \text{ GeV} \quad (\text{for } \tan \beta > 10) \]
[\[ m_h > 114.6 \text{ GeV} \quad (\text{for } 2 \leq \tan \beta \leq 8) \]
The radiatively-corrected Higgs mass

The formula for $m_h$ previously given is a tree-level formula. At one-loop, these are important corrections. The dominant corrections are due to:

\[\begin{array}{c}
t \\
\hline
h \\
\hline
t
\end{array}\]

\[\begin{array}{c}
t
\hline
h
\end{array}\]

In the SUSY limit, these two diagrams above cancel. But, due to supersymmetry breaking, there is an incomplete cancellation. A quick and dirty computation will expose the largest effect.

Recall the formula for the effective potential. Setting $\text{Str}(\bar{M}^2(\phi)) = 0$,

\[V_{\text{eff}}(\phi) = V_{\text{tree}}(\phi) + \frac{1}{64\pi^2} \text{Str} \left\{ \bar{M}^4(\phi) \left[ \ln \left( \frac{M^2(\phi)}{\Lambda^2} \right) - \frac{1}{2} \right] \right\} \]

Examine the contribution of $t$ and $\tilde{t}_L, \tilde{t}_R$ to $\text{Str}$. For simplicity, let us ignore stop mixing and put $M_2 = M_\tilde{t} = M_{\tilde{c}}$. Then,

\[m_\tilde{c}^2 = m_\tilde{t}^2 = m_{\tilde{t}_L}^2 = m_{\tilde{t}_R}^2 = M_\tilde{c}^2 + \frac{1}{2} h_{\tilde{t}^2} v^2 \]

Then, the one-loop contribution to $V_{\text{eff}}$ is:

\[V^{(1)}(v_1, v_2) = \frac{3}{64\pi^2} \cdot 2.2 \left[ (M_\tilde{c}^2 + \frac{1}{2} h_{\tilde{t}^2} v^2)^2 \left[ \ln \left( \frac{M_\tilde{c}^2 + \frac{1}{2} h_{\tilde{t}^2} v^2}{\Lambda^2} \right) - \frac{1}{2} \right] - \frac{1}{4} h_{\tilde{t}^2} v^2 \right] \]

\text{color} \quad \text{complex} \quad \text{spin-1/2 degrees of freedom}
Then,

\[ V = \frac{1}{32} (g^2 + g'^2)(v_1^2 - v_2^2)^2 + \frac{1}{8} (V_1 V_2) \begin{pmatrix} m_1^2 & -m_2^2 \\ -m_2^2 & m_1^2 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} + V^{(1)}_{(V_1, V_2)} \]

\[ \frac{\partial V}{\partial v_2} = 0 \quad \Rightarrow \quad m_2^2 = m_{12}^2 \frac{v_1}{v_2} - \frac{1}{8} (g^2 + g'^2)(v_2^2 - v_1^2) - \frac{1}{v_2} \frac{\partial V^{(1)}}{\partial v_2} \]

Using the minimum condition to eliminate \( m_2^2 \),

\[ \frac{\partial^2 V}{\partial v_2^2} = m_{12}^2 \frac{v_1}{v_2} + \frac{1}{4} (g^2 + g'^2)v_2^2 - \frac{1}{v_2} \frac{\partial V^{(1)}}{\partial v_2} + \frac{\partial^2 V^{(1)}}{\partial v_2^2} \]

Inserting our expression for \( V^{(1)} \),

\[ \frac{\partial^2 V^{(1)}}{\partial v_2^2} - \frac{1}{v_2} \frac{\partial V^{(1)}}{\partial v_2} = \frac{3}{8 \pi^2} \frac{r^2}{m^2} \ln \left( \frac{m_2^2}{m_e^2} \right) \]

Note that \( \Lambda \) has cancelled out!

The effect of the \( t \) and \( t' \) loops is to modify \( M_{22} \) of the CP-even squared mass matrix:

\[ \delta M_{22}^2 = \frac{3g^2m_e^4}{8 \pi^2 m_2^2 \sin^2 \beta} \ln \left( \frac{m_e^2}{m_t^2} \right) \]

Diagonalizing the CP-even Higgs mass matrix in the limit of \( m_A \gg m_2 \) yields the new upper limit for \( m_h \):

\[ m_h^2 \leq m_2^2 \cos^2 2\beta + \frac{3g^2 m_e^4}{8 \pi^2 m_2^2} \ln \left( \frac{m_e^2}{m_t^2} \right) \]
One can repeat the previous computation to include the effects of stop mixing. Recall the stop mass matrix:

\[ M_{\text{stop}} = \begin{pmatrix} M_0^2 + m_t^2 + D_L & m_t X_t \\ m_t X_t & M_U^2 + m_t^2 + D_R \end{pmatrix} \]

where \( D_L \) and \( D_R \) are the \( O(m_t^2) \) D-term contributions and

\[ X_t = A_t - \mu \cot \beta \]

The new upper bound, which is saturated when \( \tan \beta \gg 1 \), is given by:

\[ m_h^2 \leq m_Z^2 + \frac{3 g^2 m_t^4}{8 \pi^2 m_W^2} \left[ \ln \left( \frac{M_s^2}{m_t^2} \right) + \frac{X_t^2}{M_s^2} \left( 1 - \frac{X_t^2}{12 M_s^2} \right) \right] \]

where \( M_s^2 = \frac{1}{2} (M_{U_1}^2 + M_{U_2}^2) \).

The upper bound is maximal when \( X_t = \sqrt{6} M_s \) (which is called the "maximal mixing" point).

This result was first obtained in 1991. Since then, computations have become much more sophisticated. Complete one-loop results and nearly complete two-loop results (plus leading log resummations) lead to the conclusion that:

\[ M_h \lesssim 135 \text{ GeV} \]

assuming \( M_s \lesssim 2 \text{ TeV} \).

For further details on MSSM Higgs theory and phenomenology and references, see M. Carena and H. E. Haber, Prog. Nucl. Part. Phys.
Maximal mixing corresponds to choosing the MSSM Higgs parameters in such a way that $m_h$ is maximized (for a fixed $\tan \beta$). This occurs for $X_t/M_S \sim 2$. As $\tan \beta$ varies, $m_h$ reaches its maximal value, \((m_h)_{\text{max}} \sim 130$ GeV, for $\tan \beta \gg 1$ and $m_A \gg m_Z$.  

recent calculation including new 2-loop contributions (Brignole et al.)
Present status of the LEP Higgs Search [95% CL limits]

- Standard Model Higgs boson: \( m_h > 114.6 \) GeV
- Charged Higgs boson: \( m_{H^\pm} > 78.6 \) GeV
- MSSM Higgs: \( m_h > 91.0 \) GeV; \( m_A > 91.9 \) GeV

At large \( \tan \beta \), supersymmetric radiative corrections can also have a significant impact on the Higgs branching ratios. Example: the dominant decay mode \( h \to b\bar{b} \) is suppressed in some regions of MSSM Higgs parameter space.
UNIFICATION OF COUPLINGS

Grand unification predicts the unification of gauge couplings. Since the running of the coupling constants below the grand unified scale is dictated by the Standard Model particle spectrum, one can test the hypothesis of coupling constant unification.

A subtlety: normalization of the U(1)y coupling.

In SU(2)\(_L\) x U(1)y theory, the overall normalization of the U(1)y coupling was a matter of convention. If \( g' \) is unified in a non-abelian group, then the relative normalization of \( g \) and \( g' \) is fixed. To work out the proper normalization, consider the covariant derivative:

\[ D_\mu = \partial_\mu + ig_\alpha T^a A^a_\mu \]

At scales above unification, we have complete unification, so \( g_0 = g_0 \) and \( \text{Tr}(T_a T_b) = \text{Tr} \delta^{ab} \).

Below unification,

\[ g_0 T^a A^a_\mu = g T^3 W^3_\mu + g' \frac{Y}{2} B + \ldots \]
Coupling constant evolution

\[ \frac{d g^2_{\bar{z}}}{dt} = \frac{b_2 g^4_{\bar{z}}}{16 \pi^2} \]

**Solution:**

\[ \frac{1}{g^2_{\bar{z}}(m^2_\tau)} = \frac{1}{g^2_{\bar{z}}} - \frac{b_2}{16 \pi} \ln \left( \frac{m^2_{\bar{z}}}{M^2_X} \right) \]

\[ \frac{1}{g^2_{\bar{z}}(m^2_\tau)} = \frac{1}{g^2_{\bar{z}}} - \frac{b_2}{16 \pi} \ln \left( \frac{m^2_{\bar{z}}}{M^2_X} \right) \]

Define:

\[ \sin^2 \theta_W(m^2_\tau) = \frac{g^{12}(m^2_\tau)}{g^2(m^2_\tau) + g^{12}(m^2_\tau)} = \frac{\frac{3}{2} g^2_{\bar{z}}(m^2_\tau)}{\frac{3}{2} g^2_{\bar{z}}(m^2_\tau) + g^2_{\bar{z}}(m^2_\tau)} \]

\[ = \frac{3}{8} - \frac{5}{32 \pi} \alpha(m^2_\tau) (b_1 - b_2) \ln \left( \frac{M^2_X}{m^2_{\bar{z}}} \right) \]

\[ \ln \frac{M^2_X}{m^2_{\bar{z}}} = \frac{32 \pi}{5b_1 + 3b_2 - 8b_3} \left( \frac{3}{8\alpha(m^2_\tau)} - \frac{1}{\alpha_5(m^2_\tau)} \right) \]
Thus, at the unification point,

\[ g_v(W^3 T^3 + B T^0) = g W^3 T^3 + g' B \frac{Y}{2} \]

where \( T^0 \) is the properly normalized hypercharge generator when embedded in the grand unified group.

Thus, \( g_v = g_3 = g_2 = g_1 = g \) at the unification point

\[ T^0 = \frac{g' Y}{g_1} \frac{1}{2} \]

Using

\[ \text{Tr} (T^3)^2 = \text{Tr} (T^0)^2 \]

\[ = \frac{1}{4} \frac{g'^2}{g_1^2} \text{Tr} Y^2 \]

we conclude that

\[ \frac{g_1^2}{g_2^2} = \frac{g'^2 \text{Tr} Y^2}{4 \text{Tr} (T^3)^2} \]

\[ \Rightarrow \frac{g_1^2}{g_2^2} = \frac{5}{3} g'^2 \]

\[ \begin{array}{c|c|c|c}
2 & 4 & 0/3
\end{array} \]

[assuming one generation of the Standard Model fills up complete representations of the grand unified group.]
Introduce \[ X = \frac{1}{5} \left( \frac{b_2 - b_3}{b_1 - b_2} \right) \]

Then, we find:

\[
\sin^2 \Theta_W(m_Z) = \frac{1}{1 + 8X} \left[ 3X + \frac{d(m_Z)}{\alpha_s(m_Z)} \right]
\]

To compute the \( b_i \), we employ:

\[
b_i = \frac{2}{3} T_f(P_i) \prod_{k \neq j} d_f(P_k) + \frac{1}{6} T_s(P_i) \prod_{k \neq j} d_s(R_j)
\]

\[- \frac{11}{3} C_2(G_i) \]

\( f = \) fermion \hspace{1cm} \( s = \) scalar

\( \prod_{k \neq j} d(R_j) = \) multiplicity factors

\( d(R) = \dim(R) \)

\[ \text{Tr} \ T^a T^b = T(R) \delta^{ab} \]

\[ (T^a T^a)_{ij} = C_2(G) \delta_{ij} \]

For \( G = SU(N) \), \( C_2(G) = N \)
For \( G = U(1) \), \( C_2(G) = 0 \)

Note: using the properly normalized hypercharge generator, \( \frac{\sqrt{3}}{2} y \), it follows that:

\[ T(R_1) = \left( \sqrt{\frac{3}{2}} \frac{1}{4} y \right)^2 = \frac{3}{20} y^2 \]

Example: \[ b_3 = \frac{2}{3} \left[ \frac{1}{1} (2) + \frac{1}{2} (1) + \frac{1}{3} (1) \right] N_G - \frac{11}{3} (3) \]

\[ = \frac{4}{3} N_G - 11 \]

$N_G$ = number of fermion generations
$N_G = 3$
Final result

\[ b_3 = \frac{4}{3} N_6 - 11 \]
\[ b_2 = \frac{1}{6} N_H + \frac{4}{3} N_6 - \frac{22}{3} \]
\[ b_1 = \frac{1}{10} N_H + \frac{4}{3} N_6 \]

where I have allowed for \( N_H \) copies of the Standard Model Higgs boson.

For the Standard Model, \( N_6 = 3 \) and \( N_H = 1 \).

\[ b_3 = -7 \]
\[ b_2 = -\frac{19}{6} \]
\[ b_1 = \frac{41}{10} \]

\[ x = \frac{1}{5} \left( \frac{b_2 - b_3}{b_1 - b_2} \right) = \frac{23}{218} = 0.1055 \]

Remark: Notice that \( N_6 \) drops out completely in the expression for \( x \). (This is a special feature of the one-loop calculation). Thus, in this approximation, the success (or failure) of unification does not depend on the number of fermion generations.
Check the prediction of $\alpha_s(m_Z)$.

\[
\alpha_s(m_Z) = \frac{\alpha(m_Z)}{(1+8x)\sin^2\theta_W(m_Z) - 3x}
\]

These are $\overline{MS}$-couplings.

\[
\sin^2\theta_W(m_Z)_{\overline{MS}} = 0.2315 \pm 0.0004
\]
\[
\alpha^{-1}(m_Z)_{\overline{MS}} = 127.90 \pm 0.09
\]
\[
x = 0.1055
\]

$\Rightarrow \alpha_s(m_Z) = 0.071$

to be compared with the world average:

\[
\alpha_s(m_Z) = 0.118 \pm 0.003
\]

Is this a hint for the minimal supersymmetric standard model (MSSM)?

**Exercise:** Show that $x = \frac{1}{7}$ in the MSSM

$\Rightarrow \alpha_s(m_Z) = 0.116$

*Note: two-loop corrections to unification are not negligible. The prediction for $\alpha_s(m_Z)$ increases by roughly 0.01, not nearly enough to save Standard Model unification.*
Fig. 8. Gee-whizz plot showing how well GUT predictions of $\sin^2 \theta_w$ agree with the experimental data.

From J. Ellis (Lepton-Photon Conference, Beijing 1995)
Beyond the MSSM

A priori, there is nothing to stop us from considering extensions to the Standard Model involving new gauge or matter fields and then constructing its supersymmetric extension. The success of the SUSY-GUT prediction limits somewhat which extensions to consider.

Example: the supersymmetric extension of the four-Higgs-doublet Standard Model would not exhibit a successful unification of couplings.

Unification is not affected by the introduction of $SU(3) \times SU(2) \times U(1)$-singlet fields. Let us promote this to a superfield $\hat{N}$.

**Motivations for $\hat{N}$**

(i) The $\mu \hat{H}_1 \hat{H}_2$ term of the MSSM is puzzling. It is supersymmetric, and requires $\mu$ to be of order the supersymmetry breaking scale. How can this happen?

There are a number of proposals, but we shall not consider them here.
NMSSM

Remove the $\mu \hat{H}_1 \hat{H}_2$ term from the superpotential. Replace it with:

$$\lambda_1 \hat{H}_1 \hat{H}_2 \hat{N} + \lambda_2 \hat{N}^3$$

where $\lambda_1$ is dimensionless. One obtains an effective $\mu$, namely $\mu = \lambda_1 \langle \hat{N} \rangle$.

In this model, the number of neutralinos and neutral Higgs fields are increased.

(ii) The see-saw model of neutrino masses introduces a heavy right-handed neutrino. One can construct a supersymmetric extension of the see-saw model by introducing $\hat{N}$ as above, but with a different superpotential.

Remark: in the MSSM, R-parity conservation is imposed to guarantee L conservation in the low-energy theory. The supersymmetric see-saw model is R-parity conserving since L is violated by two units in the neutrino mass term:

$$-\mathcal{L}_m = m_{\nu} \bar{\nu} \nu + h.c.$$
In the R-Parity-Conserving (RPC) MSSM:

- $R = (-1)^{3(B-L)+2S}$
- The LSP is stable
- Neutrinos are massless

To obtain neutrino masses consistent with RPC, one must violate L by two units. The simplest model is the supersymmetric extension of the seesaw.

**One-generation model**

$$W \ni \epsilon_{ij} \left[ \lambda \hat{H}_U^i \hat{L}^j \hat{N} - \mu \hat{H}_D^i \hat{H}_U^j \right] + \frac{1}{2} M \hat{N} \hat{N}$$

$$V_{\text{soft}} \ni m_L^2 \tilde{\nu}^* \tilde{\nu} + m_N^2 \tilde{N}^* \tilde{N} + \left[ \lambda A_\nu H_U^0 \tilde{\nu} \tilde{N}^* + M B_N \tilde{N} \tilde{N} + \text{h.c.} \right]$$

After EWSB, $\langle H_i^0 \rangle = v_i / \sqrt{2}$, with $\tan \beta \equiv v_u / v_d$, one obtains the usual seesaw result:

$$\mathcal{M}_N = \begin{pmatrix} 0 & m_D \\ m_D & M \end{pmatrix}$$

where $m_D \equiv \lambda v_u$. Thus, taking $m_D \ll M$, $m_\nu \simeq m_D^2 / M$. 
The sneutrino masses are obtained by diagonalizing a $4 \times 4$ squared-mass matrix. Here, it is convenient to define:

$$\tilde{\nu} = (\tilde{\nu}_1 + i\tilde{\nu}_2)/\sqrt{2} \text{ and } \tilde{N} = (\tilde{N}_1 + i\tilde{N}_2)/\sqrt{2}. $$

Then, the squared-sneutrino mass matrix $(\mathcal{M}^2)$ separates into CP-even and CP-odd blocks:

$$\mathcal{M}^2 = \frac{1}{2} \begin{pmatrix} \phi_1 & \phi_2 \end{pmatrix} \begin{pmatrix} \mathcal{M}^2_+ & 0 \\ 0 & \mathcal{M}^2_- \end{pmatrix} \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix},$$

where $\phi_i \equiv (\tilde{\nu}_i, \tilde{N}_i)$ and $\mathcal{M}^2_\pm$ consist of the following $2 \times 2$ blocks:

$$\begin{pmatrix} m^2_{\tilde{\nu}} + \frac{1}{2} m^2_Z \cos 2\beta + m^2_D & m_D [A_\nu - \mu \cot \beta \pm M] \\ m_D [A_\nu - \mu \cot \beta \pm M] & M^2 + m^2_D + m^2_{\tilde{N}} \pm 2 B_N M \end{pmatrix}.$$  

To first order in $1/M$, the two light sneutrino eigenstates are $\tilde{\nu}_1$ and $\tilde{\nu}_2$, with corresponding squared masses:

$$m^2_{\tilde{\nu}_{1,2}} = m^2_{\tilde{\nu}_L} + \frac{1}{2} m^2_Z \cos 2\beta \mp \frac{1}{2} \Delta m^2_{\tilde{\nu}},$$

where $\Delta m^2_{\tilde{\nu}} \equiv m^2_{\tilde{\nu}_2} - m^2_{\tilde{\nu}_1}$. Writing $\Delta m^2_{\tilde{\nu}} = 2 m_{\tilde{\nu}} \Delta m_{\tilde{\nu}}$,

$$r_\nu \equiv \frac{\Delta m_{\tilde{\nu}}}{m_\nu} \simeq \frac{2 (A_\nu - \mu \cot \beta - B_N)}{m_{\tilde{\nu}}}.$$
**Three-generation model**

In the three-generation model, one can choose various alternatives depending on the number of singlet superfields $\hat{N}$. Suppose that there are $n_g$ SM generations.

- If there is only one $\hat{N}$ superfield, then
  \[ M_N = \begin{pmatrix} 0 & (m_D)_j \\ (m_D)_i & M \end{pmatrix}, \]
  where $(m_D)_i \equiv \lambda_i v_u$ [i labels generation], which yields (at tree-level) $n_g - 1$ massless neutrinos and one light neutrino with mass $m_\nu = \sum_i [(m_D)_i]^2$.

- If there are $n_g$ singlets $\hat{N}_i$, then
  \[ M_N = \begin{pmatrix} 0 & (m_D)_{\ell k} \\ (m_D)_{ij} & M_{ik} \end{pmatrix}, \]
  where $(m_D)_{ij} \equiv \lambda_{ij} v_u$, which yields (at tree-level) $n_g$ light neutrinos with nonzero mass. In this case, all light neutrinos have mass, since $\det M_N = (\det m_D)^2 \neq 0$.

In all cases, if the unperturbed ($M \to \infty$) sneutrino masses are non-degenerate, then $(\Delta m_{\tilde{\nu}})_k \neq 0$ for all $k = 1, \ldots, n_g$. 
In a general R-Parity-Violating (RPV) model, both L and B are violated. The corresponding superpotential is

\[
W = \epsilon_{ij} \left[ -\mu_\alpha \hat{L}_\alpha \hat{H}^i_u + \frac{1}{2} \lambda_{\alpha\beta m} \hat{L}_\alpha \hat{L}_\beta \hat{E}_m + \lambda'_{\alpha nm} \hat{L}_\alpha \hat{Q}_n \hat{D}_m 
- h_{nm} \hat{H}^i_u \hat{Q}_n \hat{U}_m \right] + (\lambda_B)_{pnm} \hat{U}_p \hat{D}_n \hat{D}_m ,
\]

where \( \alpha, \beta = 0, \ldots, 3; m, n, p = 1, 2, 3 \) and \( \hat{L}_0 \equiv \hat{H}_D \).

The RPC model is equivalent to introducing a \( \mathbb{Z}_2 \) matter parity. To avoid fast proton decay in the RPV model, one may introduce a \( \mathbb{Z}_3 \) triality, which conserves B. This is the unique choice for a (generation independent) discrete symmetry with no discrete gauge anomalies in a model consisting only of the MSSM superfields. [Ibanez, Ross]

\[ V_{\text{soft}} = (M^2_{Q})_{mn} \tilde{Q}_m^* \tilde{Q}_n^i + (M^2_{U})_{mn} \tilde{U}_m^* \tilde{U}_n + (M^2_{D})_{mn} \tilde{D}_m^* \tilde{D}_n \]
\[ + (M^2_L)_{\alpha \beta} \tilde{L}_\alpha^i \tilde{L}_\beta^i + (M^2_E)_{mn} \tilde{E}_m^* \tilde{E}_n + m^2_U |H_U|^2 \]
\[ - (\epsilon_{ij} b_\alpha \tilde{L}_\alpha^i H_U^j + \text{h.c.}) + \epsilon_{ij} \left[ \frac{1}{2} a_{\alpha \beta m} \tilde{L}_\alpha^i \tilde{L}_\beta^j \tilde{E}_m \right. \]
\[ + a'_{\alpha m} \tilde{L}_\alpha^i \tilde{Q}_n \tilde{D}_m - (a_U)_{nm} H_U^i \tilde{Q}_n \tilde{U}_m + \text{h.c.} \]
\[ + \frac{1}{2} \left( M_3 \tilde{g} \tilde{g} + M_2 \tilde{W}^a \tilde{W}^a + M_1 \tilde{B} \tilde{B} + \text{h.c.} \right) \]

\[ V_D = \frac{1}{8} g'^2 \left\{ \left( \left| H_U \right|^2 - \sum_\alpha \left| \tilde{L}_\alpha \right|^2 - \sum_m \left| \tilde{Q}_m \right|^2 \right)^2 - 2 \sum_{\alpha \neq \beta} \left| \epsilon_{ij} \tilde{L}_\alpha^i \tilde{L}_\beta^j \right|^2 \right\} \]
\[ + 4 \sum_\alpha \left| H_U^i \tilde{L}_\alpha \right|^2 - 2 \sum_{m \neq n} \left| \epsilon_{ij} \tilde{Q}_m^i \tilde{Q}_n^i \right|^2 \]
\[ + 4 \sum_m \left| H_U^i \tilde{Q}_m \right|^2 - 4 \sum_{\alpha m} \left| \epsilon_{ij} \tilde{L}_\alpha^i \tilde{Q}_m \right|^2 \right\} \]
\[ + \frac{1}{8} g'^2 \left[ \left| H_U \right|^2 - \sum_\alpha \left| \tilde{L}_\alpha \right|^2 + 2 \sum_m \left| \tilde{E}_m \right|^2 + \frac{1}{3} \sum_m \left| \tilde{Q}_m \right|^2 \right. \]
\[ - \frac{4}{3} \sum_m \left| \tilde{U}_m \right|^2 + \frac{2}{3} \sum_m \left| \tilde{D}_m \right|^2 \right] \]
Neutrino masses: Tree level

In the \{\tilde{B}, \tilde{W}^3, \tilde{h}_U, \nu_\alpha\} basis the $7 \times 7$ mass matrix, $M^{(n)}$ is

\[
\begin{pmatrix}
M_1 & 0 & m_Z s_W v_u / v & -m_Z s_W v_\beta / v \\
0 & M_2 & -m_Z c_W v_u / v & m_Z c_W v_\beta / v \\
m_Z s_W v_u / v & -m_Z c_W v_u / v & 0 & \mu_\beta \\
-m_Z s_W v_\alpha / v & m_Z c_W v_\alpha / v & \mu_\alpha & 0_{\alpha \beta}
\end{pmatrix}
\]

Two zero eigenvalues: two massless neutrinos

Five non-zero eigenvalues: four $\tilde{\chi}^0$ and one $\nu$

\[
\text{det}' M^{(n)} = m_Z^2 \mu^2 M_\gamma \cos^2 \beta |\hat{v} \times \hat{\mu}|^2
\]

\[
\sin^2 \xi \equiv |\hat{v} \times \hat{\mu}|^2 \equiv 1 - (\hat{v} \cdot \hat{\mu})^2 \text{ measures the alignment of } v_\alpha \text{ and } \mu_\alpha
\]

\[
m_\nu = \frac{\text{det}' M^{(n)}}{\text{det} M^{(n)}_0} = \frac{m_Z^2 \mu M_\gamma \cos^2 \beta \sin^2 \xi}{m_Z^2 M_\gamma \sin 2\beta - M_1 M_2 \mu} \sim m_Z \sin^2 \xi
\]

where $M_\gamma \equiv M_1 \cos^2 \theta_W + M_2 \sin^2 \theta_W$.

At tree level, $m_\nu \neq 0 \iff \sin \xi \neq 0$
Neutrino masses: Loop effects

Contributions at one loop:

- Lepton–slepton loops and down type quark–squark loops. Proportional to trilinear lepton number violating interactions

\[
\begin{align*}
\ell_n^- \text{ or } d_n^- & \quad \nu_m \quad \ell_n^- \text{ or } d_n^- \\
\nu_m \quad \tilde{\ell}_p^- \text{ or } \tilde{d}_p^- & \quad \nu_m \quad \tilde{\ell}_p^- \text{ or } \tilde{d}_p^-
\end{align*}
\]

- Sneutrino and neutralinos loops. Proportional to sneutrino–antisneutrino mass splitting. Exist in any model with lepton number violation

\[
\begin{align*}
\tilde{\nu}_n & \quad \nu_m \quad \tilde{\nu}_n \\
\nu_m \quad \tilde{\chi}_j^0 & \quad \nu_m \quad \tilde{\chi}_j^0
\end{align*}
\]
**Fermion–sfermion loops**

The lepton-slepton loop contribution is:

\[
(m_\nu)^{(\ell)\,qm} = \frac{1}{32\pi^2} \sum_{\ell,p} \lambda_{q\ell p} \lambda_{m_p \ell m_\ell} m_\ell \sin 2\phi_\ell \ln \left( \frac{M_{p1}^2}{M_{p2}^2} \right)
\]

\[
\sim \frac{1}{16\pi^2} \lambda_{q\ell p} \lambda_{m_p \ell} \frac{m_\ell^2}{M}
\]

since \( \sin 2\phi_\ell \ln(M_{p1}^2/M_{p2}^2) \propto m_\ell \).

The down-type quark-squark loops are similar

\[
(m_\nu)^{(q)\,qm} \sim \frac{3}{16\pi^2} \lambda'_{qdr} \lambda'_{mrd} \frac{m_q^2}{M}
\]

The dominant loops are with \( \tau \) leptons and \( b \) quarks.

General structure of the one-loop mass:

\[
(m_\nu)^{(f)} \sim (\text{loop factor}) \times (\text{RPV Yukawas}) \times \lambda_f^2
\]
Sneutrino–neutralinos loops

\[ m^{(1)}_\nu = \frac{g^2 \Delta m_\tilde{\nu}}{32\pi^2 \cos^2 \theta_W} \sum_j f(y_j)|Z_j Z|^2 \sim 10^{-3} \Delta m_\tilde{\nu} \]

where \( f(y_j) = \sqrt{y_j} [y_j - 1 - \ln(y_j)] / (1 - y_j)^2 \), \( Z_j Z \) projects out the \( \tilde{Z} \) eigenstate from \( \tilde{\chi}^0_j \), and \( y_j \equiv M^2_\nu/M^2_{\tilde{\chi}^0_j} \)

This contribution exists in any model. [Y. Grossman and H.E. Haber] The general structure of the one-loop mass:

\[ (m_\nu)^{\tilde{\nu}} \sim (\text{loop factor}) \times (\text{RPV parameters}) \]

If the sizes of the RPV parameters that enter here are roughly the same as the RPV Yukawas that contribute to \( (m_\nu)^{(f)} \), then we would expect \( (m_\nu)^{\tilde{\nu}} \) to be the dominant one-loop contribution to the neutrino mass

\[ \frac{(m_\nu)^{\tilde{\nu}}}{(m_\nu)^{(f)}} \sim \frac{1}{\lambda_f^2} \gg 1 \]

where \( \lambda_f \) is a down-type Higgs-fermion Yukawa coupling.
Sneutrino–antisneutrino mass splittings

In L-violating RPV models, $\Delta L = 1$ interactions (acting twice) yield both $\Delta L = 2$ neutrino masses and sneutrino–antisneutrino mass splitting. The latter arises as a consequence of a squared-mass term: $m^2_{\Delta L=2} \tilde{\nu} \bar{\nu} + \text{h.c.}$

One expects

- Large ($\sim m_Z$) $\Delta L = 0$ SUSY breaking mass
- Small ($\sim m_\nu$) $\Delta L = 2$ “Majorana” mass

The sneutrino squared-mass matrix is schematically

$$\begin{pmatrix} m^2_{\tilde{\nu}} & m^2_{\Delta L=2} \\ m^2_{\Delta L=2} & m^2_{\tilde{\nu}} \end{pmatrix}$$

This results in sneutrino–antisneutrino mixing and small mass splitting of order $\Delta m_{\tilde{\nu}} \sim m_\nu$. 
VIII. Constraining the MSSM

The MSSM parameter count

In the previous lecture, we constructed the MSSM. But to simplify the presentation, flavor degrees of freedom were suppressed.

Now, it is time to review the full set of parameters of the MSSM, given three generations of quarks and leptons. [Generation labels: $i, j, k = 1, 2, 3$]

Slight change of notation

$\hat{A}_1 \rightarrow \hat{A}_0$
$\hat{A}_2 \rightarrow \hat{A}_0$

the subscript indicates which right-handed quark superfield couples to $\hat{A}_1$ and $\hat{A}_2$.

$m_{12}^2 = B\mu$ the "$B$-term"

Remark on the Fayet-Iliopoulos term

Since the MSSM gauge group contains a $U(1)$ factor, I could introduce an associated Fayet-Iliopoulos term (and parameter $\xi$). I choose to omit this term. Presumably, it does not arise if $SU(3) \times SU(2) \times U(1)$ is the broken subgroup of some non-abelian grand unified group.

There exists a non-renormalization theorem that states that if $\text{Tr} T^a = 0$, then by setting $\xi = 0$ at tree level, it remains zero to all orders in perturbation theory. (Conversely, if $\text{Tr} T^a \neq 0$, there is only one renormalization at one-loop order. But it is quadratically divergent!)
Parameters of the MSSM

SUSY-conserving sector

\( g_1, g_2, g_3, \theta_{\alpha\beta\gamma} \)

\( \mu \hat{H}_D \hat{H}_U \)

\( h^\ell_{jk} \hat{H}_D \hat{L}_j \hat{E}_k \)

\( h^D_{jk} \hat{H}_D \hat{Q}_j \hat{D}_k \)

\( h^U_{jk} \hat{H}_U \hat{Q}_j \hat{U}_k \)

SUSY-breaking sector

\( B\mu H_D H_U \)

\( (h^\ell A^\ell)_{jk} H_D \tilde{L}_j \tilde{E}_k \)

\( (h^D A^D)_{jk} H_D \tilde{Q}_j \tilde{D}_k \)

\( (h^U A^U)_{jk} H_U \tilde{Q}_j \tilde{U}_k \)

\( M_D^2 H_D^\dagger H_D + M_U^2 H_U^\dagger H_U \)

\( (M_Q^2)_{ij} \tilde{Q}_i^\dagger \tilde{Q}_j + (M_L^2)_{ij} \tilde{L}_i^\dagger \tilde{L}_j \)

\( (M_D^2)_{ij} \tilde{D}_i^\dagger \tilde{D}_j + (M_U^2)_{ij} \tilde{U}_i^\dagger \tilde{U}_j + (M_E^2)_{ij} \tilde{E}_i^\dagger \tilde{E}_j \)

\( M_1 \tilde{B} \tilde{B} + M_2 \tilde{W}^a \tilde{W}^2 + M_3 \tilde{g} \tilde{g} \)
To see how to count parameters, let us first consider the Standard Model. Its parameters are:

\[ g_1, g_2, g_3, \rho, \sigma \]

Higgs sector: \( V, \lambda \)

\[ V_{\text{Higgs}} = \lambda (\phi^2 - \nu^2)^2 \]

Yukawas: \( h, h, \bar{h} \)

\[ \text{real} \quad \text{imaginary} \]

\[ 27 + 27 \]

\( \rho + \sigma \) can be regarded as the imaginary part of the strong coupling constant.

Here we have used the fact that \( \lambda \) is a 3x3 complex matrix with no special properties.

But, most of these degrees of freedom are unphysical.

In the limit of \( h = h = \bar{h} = 0 \), the Standard Model possesses an exact \( U(3)^5 \) global symmetry corresponding to three generations of the five SU(3)xSU(2)xU(1) multiplets:

\[ (V, e^-)_L, e^+_L, (u, d)_L, u^c, d^c \]

Note that by gauge invariance, I must rotate each multiplet by a unique global symmetry rotation.

So, \( U(3)^5 \) rotations leave the total \( L \) invariant if \( h = h = \bar{h} = 0 \).

If \( h, h, \bar{h} \) are non-zero, the \( U(3)^5 \) rotation does not leave \( L \) invariant. In particular, the Yukawa terms of the Lagrangian would shift. But I can also view the \( U(3)^5 \) rotation as a field-redefinition which does not alter the physical predictions of the theory.

Thus, I can use these rotations to remove unphysical degrees of freedom from the parameters.
How many degrees of freedom can be removed?

Answer: the number of parameters that define the $U(3)^5$ rotation minus the number of parameters of any subgroup of $U(3)^5$ that does leave $\mathcal{L}$ invariant (since the latter has no effect on the parameters).

$U(3)$ is parameterized by 3 angles and 6 phases.

$U(3)^5$ is parameterized by 15 angles and 30 phases.

Four global symmetries that live inside $U(3)^5$ leave $\mathcal{L}$ invariant. These are $B$ and the three separate lepton numbers $L_e, L_\mu, L_\tau$ (remember that $\nu$ is massless in the Standard Model). These are $U(1)$-phase rotations.

Thus, we started with

$$32 \text{ real } + \text{ 28 phases}$$

Using $U(1)^5 - B - L_e - L_\mu - L_\tau$, we can remove

$$15 \text{ real } + \text{ 26 phases}$$

What remains are 17 real parameters and 2 phases for a total of 19 Standard Model parameters.

In fact, we can explicitly identify them:

$g_1, g_2, g_3, \theta_{\alpha\beta}, m_H, m_Z$, 6 quark masses, 3 lepton masses, 3 CKM mixing angles and 1 CKM phase,

for a total of 19 parameters.
The MSSM count

\[ z, g_1, g_2, g_3, \theta_{2\alpha} \]

3 + 1

\text{gaugino masses}

\[ M_1, M_2, M_3 \]

3 + 3

2

\[ B, \mu \]

2 + 2

\[ h_u, h_d, h_E \]

27 + 27

\[ A_u, A_d, A_E \]

27 + 27

\[ M_{\tilde{e}}, M_{\tilde{\nu}}, M_0, M_1, M_2, M_{\tilde{e}} \]

30 + 15

\[ \frac{94 + 75}{\text{equivalently:}} \]

\[ V_i \text{ and } V_d \]

or

\[ V \text{ and } \tan \beta \]

\[ \text{note:} \]

a 3x3 hermitian matrix contains 6 real parameters and 3 imaginary parameters.

Removing unphysical degrees of freedom

This time, I apply the U(3)^S rotation to the five

\[ SU(3)\times SU(2)\times U(1) \] supermultiplets:

\[ \tilde{L}, \tilde{E}, \tilde{\nu}, \tilde{\tau}, \tilde{B} \]

In this way, I protect supersymmetric interactions such as \( A^* Y A \) th.c., since I am rotating simultaneously the partners and super-partners.

Among the U(3)^S rotations, only \( B \) and \( L \) leave \( \tilde{L}_{MSSM} \) invariant. Note that \( L_e, L_\nu, \) and \( L_\tau \) are not separately conserved, assuming that sneutrinos are not mass-degenerate.

We can introduce CKM-like rotations in the slepton sector which need not align with the corresponding definitions of \( L_e, L_\nu, L_\tau \).
Using $U(3)^S-B-L$, we can remove 15 real + 28 phases.

There are two other global symmetries that we can use to remove degrees of freedom. They correspond, respectively, to global chiral symmetries that protect gaugino and higgsino masses while leaving $\lambda^\dagger A^\dagger A^\dagger$ (h.c.) interactions and $\mu H^\dagger H^\dagger$ invariant. Consider these $U(1)$ transformations:

<table>
<thead>
<tr>
<th></th>
<th>$U(1)_R$</th>
<th>$U(1)_{PQ}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\tilde{Q}, \tilde{U}, \tilde{D}, \tilde{E}$</td>

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Here, I pretended that the parameters also rotate under the $U(1)$ transformation, and chose the corresponding $U(1)$ quantum numbers that make $L$ invariant. Of course, the parameters do not rotate, so if they have a non-zero entry above, this means that the parameter shifts under the $U(1)$-rotation, and the latter can be used to remove unphysical degrees of freedom.
We therefore use $U(1)_R$ to remove a phase from $M_3$, and we use $U(1)_{pq}$ to remove a phase from $m_{12}^2 = B \mu$.

In fact, we have implicitly performed this last step, when we studied the Higgs sector and noticed that we could redefine the phases of the Higgs fields such that $m_{12}^2$ was real and $\nu_1, \nu_2 > 0$.

**Note:** As a result, the tree-level MSSM Higgs sector is automatically CP-conserving.

The final count

79

Note in particular 36 super-CKM angles and 40 super-CKM phases. These arise since squarks and sleptons need not be diagonal in the basis in which quarks and leptons are diagonal.
Unconstrained Low-Energy SUSY is not Viable

- No conservation of lepton numbers $L_e$, $L_\mu$ and $L_\tau$
- Unsuppressed flavor-changing neutral-currents
- New sources of CP-violation in conflict with experimental constraints

The MSSM is a phenomenologically viable theory only in tiny "exceptional" regions of the full parameter space. That is, there needs to be many \textit{a priori} unexplained small (soft-SUSY-breaking) parameters in the model.

In the bottom-up approach, one attempts to assess the viable parameter regimes and deduce implications for the fundamental theory of SUSY-breaking.

In the top-down approach, one looks for simple theories of SUSY-breaking that yield acceptable low-energy SUSY parameters.
Examples of the bottom-up approach

Place constraints directly on the ("low-energy") MSSM parameters. Two alternatives are:

1. Horizontal universality

Take $M_0^s, M_0^s, M_0^s, M_0^s, M_0^s$ and the associated matrix $A$-parameters to be proportional to $I_{3 	imes 3}$.

2. Flavor alignment

Take $M_0^s, M_0^s, M_0^s, M_0^s, M_0^s$ are the associated matrix $A$-parameters to be flavor diagonal in a basis where the quark and lepton mass matrices are flavor diagonal.

These alternatives are phenomenologically viable, but rather ad-hoc from a theoretical perspective.

The top-down approach

The MSSM parameters evolve with energy scale according to renormalization group equations (RGE's). Impose a particular (simple) structure on the soft-SUSY-breaking terms at a common high energy scale (e.g. $M_{Pl}$).

The initial conditions depend on the theory of supersymmetry breaking. Then, using RG-evolution, one can compute the low-energy SUSY spectrum.

possible bonus: radiative electroweak symmetry breaking
Evolution of SUSY parameters - the SUSY RGE's

notation:

\[ \begin{align*}
a_t &= h_t A_t \\
a_b &= h_b A_b \\
a_c &= h_c A_c \\
b &= B \mu \\
Y_t &= 2h_t^2 (m_{H^+_t}^2 + m_{\tilde{q}_3}^2 + m_{\tilde{\nu}_3}^2) + 2a_t^2 \\
Y_b &= 2h_b^2 (m_{H^+_b}^2 + m_{\tilde{q}_3}^2 + m_{\tilde{D}_3}^2) + 2a_b^2 \\
Y_c &= 2h_c^2 (m_{H^+_c}^2 + m_{\tilde{L}_3}^2 + m_{\tilde{e}_3}^2) + 2a_c^2 \\
\frac{d\mu}{dt} &= \mu \frac{d}{d\mu} \\
\mu &= \text{evolution scale} \end{align*} \]

Keeping just the 3rd generation Yukawas, and assuming all parameters real,

\[ \begin{align*}
\frac{dh_t}{dt} &= \frac{h_t}{16 \pi^2} \left[ 6h_t^2 + h_b^2 - \frac{16}{3} g_2^2 - 3g_t^2 - \frac{13}{15} g_1^2 \right] \\
\frac{dh_b}{dt} &= \frac{h_b}{16 \pi^2} \left[ 6h_b^2 + h_t^2 + h_c^2 - \frac{16}{3} g_3^2 - 3g_b^2 - \frac{2}{15} g_1^2 \right] \\
\frac{dh_c}{dt} &= \frac{h_c}{16 \pi^2} \left[ 4h_c^2 + 3h_b^2 - 3g_1^2 - \frac{9}{5} g_t^2 \right] \\
\frac{d\mu}{dt} &= \frac{\mu}{16 \pi^2} \left[ 3h_t^2 + 3h_b^2 + h_c^2 - 3g_1^2 - \frac{3}{5} g_t^2 \right] \\
\mu &= \text{supersymmetric Higgs mass parameter.} \end{align*} \]
\[
\frac{d}{dt} M_a = \frac{b_a g_a^2 M_a}{8\pi^2}
\]

\[
\frac{d}{dt} g_a = \frac{b_a g_a^3}{16\pi^2}
\]

Thus, \[
\frac{d}{dt} \left( \frac{M_a}{g_a^2} \right) = 0 \quad \text{[at one-loop only]}
\]

In grand unified models, both \( g_a \) and \( M_a \) unify at the grand unification scale, \( M_X \). That is,

\[
g_a(M_X) = g_\nu
\]

\[
M_a(M_X) = M_\nu
\]

Then,

\[
\frac{M_1}{g_1^2} = \frac{M_2}{g_2^2} = \frac{M_3}{g_3^2} \quad \text{at any scale.}
\]

E.g.

\[
M_3 = \frac{g_3^2}{g_2^2} M_2 \approx 3.5 M_2 \quad \text{gluino mass}
\]

\[
M_1 = \frac{5}{3} \frac{g_1^2}{g_2^2} M_2 \approx 0.5 M_2 \quad \text{bino mass (often the lightest SUSY particle)}
\]
$$\frac{16\pi^2 \text{dax}}{dt} = a_t \left[18h_t^2 + h_t^2 - \frac{16}{3} g_2^2 - 3g_1^2 - \frac{13}{15} g_1^4\right]$$

$$+ 2a_t h_t h_t + h_t \left[\frac{32}{3} g_2^2 M_3 + 6 g_2^2 M_2 + \frac{16}{15} g_1^2 M_1\right]$$

$$\frac{16\pi^2 \text{dab}}{dt} = a_b \left[18h_b^2 + h_t^2 + h_t^2 - \frac{16}{3} g_2^2 - 3g_1^2 - \frac{7}{15} g_1^4\right]$$

$$+ 2a_t h_b h_b + 2a_t h_t h_b + h_b \left[\frac{32}{3} g_2^2 M_3 + 6 g_2^2 M_2 + \frac{16}{15} g_1^2 M_1\right]$$

$$\frac{16\pi^2 \text{dar}}{dt} = a_r \left[12h_r^2 + 3h_b^2 - 3g_2^2 - \frac{9}{5} g_1^4\right]$$

$$+ 6a_b h_b h_r + h_r \left[6g_2^2 M_2 + \frac{18}{5} g_1^2 M_1\right]$$

$$\frac{16\pi^2 \text{db}}{dt} = b \left[3h_t^2 + 3h_b^2 + h_r^2 - 3g_1^2 - \frac{3}{5} g_1^4\right]$$

$$+ \mu [6a_t h_t + 6a_b h_b + 2a_t h_r + 6g_2^2 M_2 + \frac{6}{5} g_1^2 M_1]$$

$$\frac{16\pi^2 \text{dme}_{Z_1}^2}{dt} = Y_t + Y_b - \frac{32}{3} g_2^2 M_3^2 - 6 g_2^2 M_2^2 - \frac{2}{15} g_1^2 M_1^2$$

$$\frac{16\pi^2 \text{dme}_{Z_3}^2}{dt} = 2Y_e - \frac{32}{3} g_2^2 M_3^2 - \frac{32}{15} g_1^2 M_1^2$$

$$\frac{16\pi^2 \text{dme}_{F_1}^2}{dt} = 2Y_b - \frac{32}{3} g_2^2 M_3^2 - \frac{8}{15} g_1^2 M_1^2$$

$$\frac{16\pi^2 \text{dme}_{F_3}^2}{dt} = Y_t - 6 g_2^2 M_2^2 - \frac{6}{5} g_1^2 M_1^2$$

$$\frac{16\pi^2 \text{dme}_{W}^2}{dt} = 2Y_t - \frac{24}{5} g_1^2 M_1^2$$
For the first two generations, the soft-SUSY-breaking squared-masses obey
\[ 16\pi^2 \frac{d m_{\phi}^2}{d t} = -\sum_a 8g_a^2 C_a^\phi M_a^2 \]
where:
\[
C_3^\phi = \begin{cases} 
4/3 & \text{for } \phi = \tilde{\chi}, \tilde{\nu}, \tilde{\tau} \\
0 & \text{for } \phi = \tilde{\chi}, \tilde{\nu}, H_0, H_d
\end{cases}
\]
\[
C_2^\phi = \begin{cases} 
3/4 & \text{for } \phi = \tilde{\chi}, \tilde{\nu}, H_0, H_d \\
0 & \text{for } \phi = \tilde{\nu}, \tilde{\chi}, \tilde{\nu}
\end{cases}
\]
\[
C_1^\phi = \frac{3}{20} y_\phi^2 \quad \text{where } y_\phi \text{ is the hypercharge of } \phi.
\]

Finally, the soft-SUSY-breaking squared-masses for $H_0$ and $H_d$ satisfy:
\[ 16\pi^2 \frac{d m_{H_0}^2}{d t} = 3 Y_t - 6g_2^2 M_2^2 - \frac{6}{5} g_1^2 M_1^2 \]
\[ 16\pi^2 \frac{d m_{H_d}^2}{d t} = 3 Y_b + Y_t - 6g_2^2 M_2^2 - \frac{6}{5} g_1^2 M_1^2 \]

Since $Y_t = 2 h_t^2 (m_{H_u}^2 + m_{\tilde{u}_3}^2 + m_{\tilde{d}_3}^2) + 2 a_t^2$ and $h_t \sim 1$, we see that $\frac{d m_{H_u}^2}{d t} > 0$. That is, $m_{H_u}$ decreases as one evolves from the high energy scale to the low-energy scale. Thus, $m_{H_u}^2$ will be the first squared-mass to be driven negative, thus triggering electroweak symmetry breaking. This is a feasible mechanism because $h_t$ is of $O(1)$, or equivalently because $m_{H_u}$ is so large.
Constraining SUSY—Top-down

Models of SUSY-Breaking

Gravity-mediated SUSY-breaking

- SUSY-breaking effects mediated by Planck-scale physics

- The minimal model (mSUGRA) assumes a universal scalar mass, $m_0$, a universal gaugino mass, $m_{1/2}$, and a universal $A$-parameter, $A_0$ at the Planck scale. In addition, the parameters $\mu$ and $B$ can be traded in for the Higgs vevs, $v_d$ and $v_u$, with a two-fold ambiguity in $\text{sign}(\mu)$. The $W$ mass fixes $v_d^2 + v_u^2 = (246 \text{ GeV})^2$, while $\tan \beta \equiv v_u/v_d$ remains a free parameter.

- Use RGEs to predict the MSSM spectrum. In particular,

$$M_3 = (g_3^2/g_2^2)M_2, \quad M_1 = (5g_1^2/3g_2^2)M_2 \approx 0.5M_2$$

- $m_{3/2} \sim 1 \text{ TeV}; \tilde{g}_{3/2}$ is irrelevant for phenomenology.
Anomaly-mediated SUSY-breaking (AMSB)
Randall and Sundrum
Gribov, Luty, Murayama and Rattazzi

- A model-independent contribution to super-partner masses (and $A$-terms) arises from the super-conformal anomaly of supergravity.

- If tree-level gaugino masses are absent, then

$$M_i \sim \frac{b_i g_i^2}{16 \pi^2 m_{3/2}},$$

where $b_i$ are the coefficients of the MSSM gauge beta-functions: $(b_1, b_2, b_3) = (33/5, 1, -3)$.

Gauge-mediated SUSY-breaking (GMSB)
Dine, Nelson and Shirman

- SUSY-breaking effects mediated by gauge forces generated at intermediate-scales (between $m_Z$ and $M_{PL}$)

- $m_{3/2} \sim 1$ eV–1 keV with phenomenological consequences
